Overview

(1) Association Analysis

Identifying significant marker-trait linkages in complex populations

(2) Genomic Selection
 Predicting breeding value of an individual based
 on kinship and genotype

(3) Preparing Data

(4) Resources

(5) Practical Examples

At the end of this module you will be able to:

Describe Association Analysis and Genome Wide Selection (GWS)

Define and estimate a Breeding Value

Define a multiple trait index

Prepare data for AA and GWS

Know how to access demonstrations and practical exercises.

Definitions

Association Analysis

Mapping in unstructured populations

Marker Assisted Selection (MAS) Selection based on Marker-QTL linkage Direct selection Selection for coupling-phase recombination Background genome selection for accelerated BC Selection for multiple QTL, etc...

Genomic Selection (GWS)

Selection based on breeding value Random effects models and BLUPs Estimate breeding value for markers and individuals

Association Analysis

Proposed as a way to overcome limitations of working with bi-parental populations for QTL-based discovery and subsequent MAS

In complex populations the magnitude of QTL effects tend to be small

Relevance of the complex population to applied goals remains an issue (e.g. inbred lines vs hybrids)

Association Analysis

Data

Vector of trait values from phenotypic evaluation of a large complex population (best if these are BLUPs)

Matrix of Markers

Matrix of population structure (STRUCTURE or PCA)

Kinship matrix

Models can estimate the contribution of STRUCTURE and Kinship to the trait and Marker-Trait linkage...

F-test for significance = $N(1-2r)^2g^2$ N = population size; r = recombination distance (marker to QTL; g^2 = proportion of variance explained by QTL

Within the context of breeding programs, success with association analysis and therefore subsequent MAS will depend on:

(1) population structure;

(2) segregation of the trait within sub-populations;

- (3) allelic diversity for the trait of interest;
- (4) size of the population;
- (5) size of the sub-populations within the larger population;
- (6) the magnitude of the QTL (proportion of variance explained).

Recommendation:

(1) Skip association mapping in germplasm collections and focus on Nested Associated Mapping (NAM) style populations A x B; A x C; A x D; individual breeding programs, etc...

(2) Use large populations

Selecting based on molecular markers

Marker Assisted Selection - a subset of statistically significant marker—trait associations are discovered, validated and used for selection

Single markers linked to QTL Haplotypes linked to QTL

MAS – based on marker –trait linkage

Genome Wide Selection - prediction of performance without evidence of statistically significant association. Single markers Haplotypes

GWS – based on sum of breeding values estimated for all markers

Genomic selection (GS)

Selection decisions based on genomic breeding values estimated as the sum of the effects of markers across the genome (Contrast to MAS in which only markers positively associated with trait are used).

Breeding values are derived from Best Linear Unbiased Predictors (BLUPs) as the sum of BLUPs for all markers.

Can estimate the breeding value of an individual, even when there are no observations (e.g. Dairy Sire example).

Genomic Selection

Breeding Value: The part of an individual's phenotypic value that is due to additive genetic effects. The value of an individual as a parent.

Assign a breeding value to each marker, regardless of significance...

GEBV = $\sum_{i}^{n} \mathbf{X}_{i} \mathbf{g}_{i}$ Genomic Estimated Breeding Value is the sum of all marker effects for an individual

Conceptual change:

Think of the value of a line based on its potential contribution to the next cycle of breeding vs its performance (Breeding vs Seeds/Commercial)

Animal Agriculture: Dairy farms purchase sperm based on its breeding value not performance. In contrast seed is purchased based on performance.

Breeding progress is based on gain under selection.

Implications

Significance of Marker-Trait (QTL) association (linkage) is less important than the estimated breeding value

We need to start thinking about Marker-QTL linkages as random effects

effects (markers) > than phenotypic observations effects are estimated as BLUPs

Estimates of breeding value are strengthened by data from relatives, therefore pedigrees, kinship matrices, etc... improve estimates of breeding values.

Data:

Vector (or matrix) of trait-value (best if phenotypes are BLUPs) Matrix of kinship (pedigree or marker-based) n x n Matrix of Markers (n x k)

SNP scoring:

markers are scored 0 or 1; heterozygotes would be 0.5; could also be number of "common" alleles (0 = homozygous for rare allele; 1 = hetero; 2 = homozygous for common allele)

Approaches:

Step-wise regression $\gamma = \beta_0 + \beta_1 X_1 + \in; \gamma = \beta_0 + \beta_2 X_2 + \in; etc...$

Multiple linear regression $\gamma = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 \ldots \in$

Multiple linear regression with correction/penalty

Ridge Regression LASSO Bayesian (various e.g. Bayesian-LASSO, etc...)

Comparing Stepwise with Multiple Regression (statistically naïve thought experiment)

0	0.1866	0.0001	0.0524	0	0.919
1	-0.1866	-0.0001	-0.0524	0	-0.919

Correction (regularization) involves introducing a penalty that places bounds on the regression

Marker homogeneous or marker-specific corrections

Ridge Regression (Tikhonov regularization) adds a constant λ to the diagonal of the matrix of coefficients makes solution unique shrinks estimates of marker effects toward 0 $\lambda = \sigma^2_{\epsilon} / \sigma^2_{\beta}$

Estimating the correction factor requires sampling the data.

Marker homogeneous correction

RR-BLUP, Estimates of marker effects are penalized to the same extent; may not be appropriate if markers are located in regions of the genome that are not associated with genetic variance

Marker-specific correction

Least Absolute Value Selection & Shrinkage Operator (LASSO-BLUP)

Bayesian Linear Regression

Conceptual Diagram of GWS (adapted from Fig. 1, Heffner, Sorrells, and Jannink, 2009. CROP SCIENCE, VOL. 49)

Genomic selection is based on a prediction of breeding value

Accuracy depends on the size of the training population, number of markers, heritability of the trait, and the number of genes contributing to the trait

We can control the population size (and composition)

The number of markers is no longer limiting (SolCAP infinium Array, Genotyping by Sequencing, etc...)

The process is iterative, with statistical models re-estimated after each cycle of phenotypic evaluation

The relative efficiency of GWS will often be lower than direct phenotypic selection; value is to select during rapid generation turn over such that multiple cycles of selection can occur. The issue of what to select for remains...

GEBV = $\sum_{i}^{n} X_{i} g_{i}$ is estimated for one trait, but how do we combine traits?

Multi Trait Index (MTI): Linear combination of observations used to compute a criterion for selection

Yield – directly valued Color – directly valued in contracts in the midwest Soluble Solids (BRIX) – value? Disease resistance – value tied to yield loss or insurance adjustment?

Selection criteria are combined into a measure of net merit weighted based on the relative importance of all traits; will differ between breeding programs due to breeding goals and market demands.

Multi Trait Index

TomatoAnalyzer - AD04 IBC 8082 S.tmt

Dpen Image

Save Fruit 🔹 🧮 Export Data 🛛 🖽 Fit size 🔹 🔊 Analyze 🚺 Revise 🔹

We can measure color as: L, a, b, Hue, chroma, G, R, B, luminosity, % red tissue, % yellow tissue, etc...

Which measurements should we select for?

Power of association Studies R-package IdDesign http://cran.r-project.org/web/packages/IdDesign/

IdDesign documentation

http://cran.r-project.org/web/packages/ldDesign/ldDesign.pdf

See example script under "Practical Exercises"; Hayes, 2007. QTL Mapping, MAS, and Genomic Selection, Short Course Sponsored by Dept. of Animal Sciences and Animal Breeding and Genetics Group, Iowa State University http://www.ans.iastate.edu/section/abg/shortcourse/notes.pdf

Other functions: Id.design , Id.power, Id.sim, etc... Determining the power of association analysis using the R-package IdDesign Rod Ball, Scion Research

> luo.ld.power(n, p, q, D, h2, phi, Vp , alpha, print.it = TRUE, missclass.rate = 0))

function = luo.ld.power after (Luo, 1998, Heredity 80, 198–208) # *n* number of individuals genotyped and phenotyped # p frequency of Bi-allelic marker linked to the QTL # *q* frequency Bi-allelic QTL (gneraly p = q) # D Linkage disequilibrium coefficient # r² from LD analysis can be converted to D; $D = [p(1-p)(q(1-q)r^2)^{1/2}]^{1/2}$ # h2 QTL `heritability'; proportion of variance explained by the QTL (Vm/Vp) *# phi* Dominance ratio: = 0 for additive, = 1 for dominant allele effects # Vp phenotypic variance; an arbitray number can be used (Vp = 100) # *alpha* Significance level for hypothesis tests

Genomic prediction based on molecular markers and kinship using the BLR package in R Paulino Pérez, Gustavo de los Campos, José Crossa, and Daniel Gianola http://genomics.cimmyt.org/

GENOMIC SELECTION AND PREDICTION IN PLANT BREEDING

DESCRIPTION

NAMESPACE

Loading Sample Data

```
infilepath <- "C:/PATH/wheat.RData"
load(infilepath)
ls()
# BEFORE RUNNING THE DATA FRAME LOOKS LIKE THIS
# [1] "A" "infilepath" "sets" "X" "Y"</pre>
```

```
library(BLR)
Load(wheat)
```

```
### Creates a testing set with 100 observations
whichNa<-sample(1:length(y),size=100,replace=FALSE)
yNa<-y
yNa[whichNa]<-NA</pre>
```

#AFTER RUNNING THE DATA FRAME LOOKS LIKE THIS
> ls() # used to display the files in the dataframe
[1] "A" "COR.trn" "COR.tst" "fm" "infilepath"
[6] "MSE.trn" "MSE.tst" "sets"
[9] "whichNa" "X" "y" "Y" "yNa"

The file fm has the information we want!

>data = fm
>attach(data)
> ls(data)
[1] "bL" "burnIn" "fit" "lambda" "mu" "nIter" "prior"
[8] "SD.bL" "SD.u" "SD.yHat" "tau2" "thin" "u" "varE"
[15] "varU" "weights" "whichNa" "y" "yHat"

Writing output to files

```
> data2 = bL
```

> write.csv(data2, "C:/PATH/data2.csv")

> data3 = u

- > write.csv(data3, "C:/PATH/data3.csv")
- > data4 = yHat
- > write.csv(data4, "C:/PATH/data4.csv")

Concluding remarks:

Accurate and objective phenotypes remain a limiting factor for tomato

Most of the changes in breeding strategy that will improve the power/efficiency of GWS will also improve traditional phenotype-based breeding

Use BLUPs to estimate trait values

Use pedigree/kinship information to strengthen estimates of breeding values of individuals based on trait BLUPs

Use larger populations
